# Environment maps

- Environment maps are commonly used for modeling natural lighting to create realistic images.
- Complex real-world illumination can be represented efficiently by environment maps.
- High quality rendering of scenes under image-based lighting requires efficient sampling strategies.

# Sampling strategies

- Environment map sampling
- Bidirectional Reflectance Distribution Function (*BRDF*) sampling
- Product sampling
- Multiple Importance Sampling (*MIS*) [33]

# Motivation

- Most of the environment map sampling methods can be used in Monte Carlo simulations but they are not suitable for real-time rendering.
- We introduced a new method based on Kd-tree structure that can be used in real-time Monte-Carlo simulations.

## Inversion method

- Inversion method is based on the observation that cumulative distribution functions (CDFs) range uniformly over the interval  $(0, 1)$
- If  $u$  is a uniform random number on  $(0, 1)$ , then using  $X = F^{-1}(u)$  generates a random number  $X$  from a distribution with specified CDF  $F$ .

# Overview I

- An environment map defined as a  $w \times h$  rectangular block can be treated as a bivariate probability distribution after normalization.

# Overview I

- An environment map defined as a  $w \times h$  rectangular block can be treated as a bivariate probability distribution after normalization.
- This rectangular block is divided into sub-blocks using a Kd-tree structure.

# Overview I

- An environment map defined as a  $w \times h$  rectangular block can be treated as a bivariate probability distribution after normalization.
- This rectangular block is divided into sub-blocks using a Kd-tree structure.
- Empirical probabilities corresponding to each sub-block are obtained as sum of the normalized pixel intensities within each sub-block.

# Overview I

- An environment map defined as a  $w \times h$  rectangular block can be treated as a bivariate probability distribution after normalization.
- This rectangular block is divided into sub-blocks using a Kd-tree structure.
- Empirical probabilities corresponding to each sub-block are obtained as sum of the normalized pixel intensities within each sub-block.
- These empirical probabilities are then sorted in descending order and corresponding block indices are assigned in increasing order.

# Overview I

- An environment map defined as a  $w \times h$  rectangular block can be treated as a bivariate probability distribution after normalization.
- This rectangular block is divided into sub-blocks using a Kd-tree structure.
- Empirical probabilities corresponding to each sub-block are obtained as sum of the normalized pixel intensities within each sub-block.
- These empirical probabilities are then sorted in descending order and corresponding block indices are assigned in increasing order.

## Overview II

- The plots of these probabilities against sub-block indices can be considered as empirical distribution of these sub-block indices.

## Overview II

- The plots of these probabilities against sub-block indices can be considered as empirical distribution of these sub-block indices.
- Representing the empirical distribution of sub-blocks in this way provides a good ground for modeling this empirical distribution by a simple probability density function (pdf).

## Overview II

- The plots of these probabilities against sub-block indices can be considered as empirical distribution of these sub-block indices.
- Representing the empirical distribution of sub-blocks in this way provides a good ground for modeling this empirical distribution by a simple probability density function (pdf).
- The resulting estimated model can be used to generate samples for incoming light.

- Select a sub-block to split further.
- Choose a splitting plane for this sub-block.
- Split the sub-block and add the resulting sub-blocks into the list.
- Repeat until a predefined number of sub-blocks are created.

# Kd-tree Construction

- Keep a list of current sub-blocks.
- Select a sub-block to split further.
- Choose a splitting plane for this sub-block.
- Split the sub-block and add the resulting sub-blocks into the list.
- Repeat until a predefined number of sub-blocks are created.

## Choosing a sub-block for splitting

- Choosing the most convenient sub-block for splitting needs a special handling.
- We proceed to choose the sub-block having the largest intensity variation first.
- Various measures of variation can be used for this purpose.
- We tested for range, variance and sum of squared error measures respectively.

(d)

**Figure 1 :** Rendered environment maps (Uffizi) (a):  $2048 \times 1024$  resolution environment map requiring 8MBs of memory. (b), (c), (d): Same environment map compressed to 48KB (1:170 compression) using range, variance, and SSE criteria, respectively. Environment maps used in this work are a courtesy of Debevec.

# SSE

In this work, we propose to use SSE which is defined by

$$SSE = \sum_{i=1}^{w_b} \sum_{j=1}^{h_b} (f_{ij} - \bar{f})^2, \quad (1)$$

as a selection criterion where  $\bar{f}$  is the sub block mean,  $w_b$  and  $h_b$  are the sub-block dimensions.

## Splitting a selected sub-block

The splitting plane position is determined in such a way that the pooled variance [16] of the children blocks is minimum. It can be shown that minimization of the pooled variance can be reduced to maximizing the sum of squares of sub-block totals divided by their respective number of pixels.

# Approximating the Empirical Distribution

Empirical block probabilities are sorted in descending order. Therefore, the corresponding pdf is expected to be an exponential type distribution. We approximate this pdf by the following monotonically decreasing function

$$p(x) = \frac{1}{\log\left(1 + \frac{n}{\alpha}\right)(\alpha + x)}, 0 \leq x \leq n, \quad (2)$$

where  $n$  is the total number of sub-blocks in the kd-tree, and  $\alpha$  is the parameter of the distribution.

Figure 2 : Empirical pdfs of various environment maps and fitted analytical pdfs for uffizi(left) and doge2(right) environment maps.

## Summary of preprocessing steps

- Construct the Kd-tree.
- Average sub-block intensities in the kd-tree are sorted in descending order to obtain the empirical pdf of the block indices.
- The empirical pdf is then approximated by an analytical model.
- The parameter of the pdf and the sub-block bounds are stored for use in the sampling procedure.

## Block selection

- Our importance sampling strategy simply consists of generating sub-block indices first and then generating incoming light direction within this block.
- Sub-block indices can be generated using the well-known probability integral transformation method of obtaining random samples from a known distribution.
- The following inverse function of the cdf is used for generating sub-block indices:

$$x = P^{-1}(\xi) = \alpha \left( \left( 1 + \frac{n}{\alpha} \right)^\xi - 1 \right), \quad (3)$$

where  $\xi$  is a uniform  $(0,1)$  random variable.

# Light direction sampling

- We know that the approximated PDF is uniform within the selected sub-block.
- Light direction can easily be generated by uniformly sampling the elevation and azimuth angles.
- Within the bounds of the sub-block, we generate two uniform random variables corresponding to elevation and azimuth angles to obtain a random incoming light direction.

# Summary of environment map sampling

- Generate three random variables:  $\xi_1, \xi_2, \xi_3$ .
- Select the corresponding block index  $x = P^{-1}(\xi_1)$ .
- Read the bounds of the selected sub-block.
- Generate elevation and azimuth angles uniformly within the bounds of the selected sub-block using  $\xi_2, \xi_3$ .
- The probability of this sample can be computed with  $p(x)/\text{Area}(\text{sub-block})$ .

- Real-time rendering implementations of our method and inversion method were made using OpenSceneGraph [4], NVIDIA CUDA [24], and Random123 [30] libraries.
- Our method, and the inversion method were also implemented using Physically Based Rendering Toolkit (PBRT) [26] for off-line renderings.
- All programs were executed on an Intel Core i7-920 (2.67 GHz) with 12GBs of RAM and NVIDIA GeForce GTX 480 GPU.

**Figure 3 :** Comparison of inversion method (left) and our method (right) in real-time rendering. In this scene, the chrome-steel teapot has been rendered with both methods using 16 samples/pixel for testing real-time rendering performance.

Figure 4 : Comparison of our method and inversion method in real-time rendering. Both of the methods were rendered with 16 samples/pixel. The FPS rates are measured under different environment maps.

Figure 5 : FPS rates of our method and the inversion method for different sample sizes and environment maps.

**Figure 6 :** Rendered spheres based on different materials and different sampling methods. rows show different materials and columns show reference images, inversion method, and kd-tree method respectively. Insets show the scaled difference between the methods and reference images.

Our kd-tree based importance sampling method:

- is more suitable than inversion method for real-time rendering;
- can handle every type of material including anisotropic materials;
- can be extended to multi-dimensional functions such as BRDFs.
